

Why unlabeled graph matching misidentified alanine

A Fragment misidentified as alanine

B Element identities hidden

Early molfind assigned this fragment to alanine after matching its formula and unlabeled graph shape. (A) Element colors reveal different chemical connectivity. (B) Hiding element identity illustrates the false positive. The correction required categorical atom-element and bonded-element-pair matching. GPU pipelines can screen candidates with counts or fingerprints, but named identities require element-aware connectivity verification.
